EUMETSAT CWG workshop, 6 – 8 April 2021 (remote)

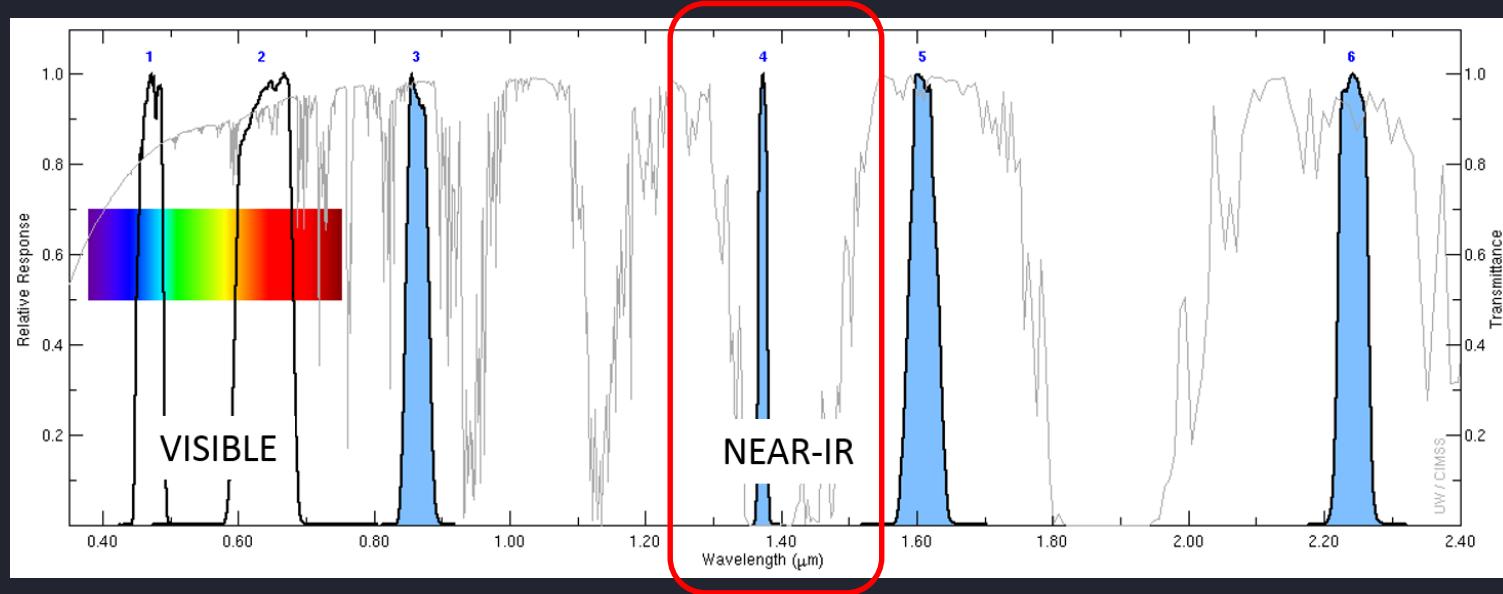

Topics of the study:

- familiarization with the 1.38 µm band properties
- visualization of the 1.38 µm band data, image enhancement options
(more details on this topic in my MTG 3T [workshop presentation](#))
- applicability of this band to storm-top observations:
 - above-anvil cirrus plumes – their structure and extent beyond the regular anvil periphery (???)
 - storm anvil details and extent, detection of thinnest parts of these, comparison to other thin cirrus detection options
 - storm tops in Cloud type RGB

1.38 µm spectral band:

- strong attenuation by tropospheric moisture >>> thin cirrus detection, high clouds discrimination
- used either as stand-alone black & white images, or included as red component in the Cloud Type RGB
- presently available:
 - MODIS instrument on Terra and Aqua
 - VIIRS instrument of NPP and JPSS satellites (NOAA-20 and on),
 - ABI instrument of GOES-R series satellites (GOES 16 and on),
 - AGRI (FY-4A series), AMI (GEO-Kompsat-2A)
 - **not included on AHI (Himawari 8/9)**
- future availability:
 - MTG-I FCI
 - EPS-SG METimage

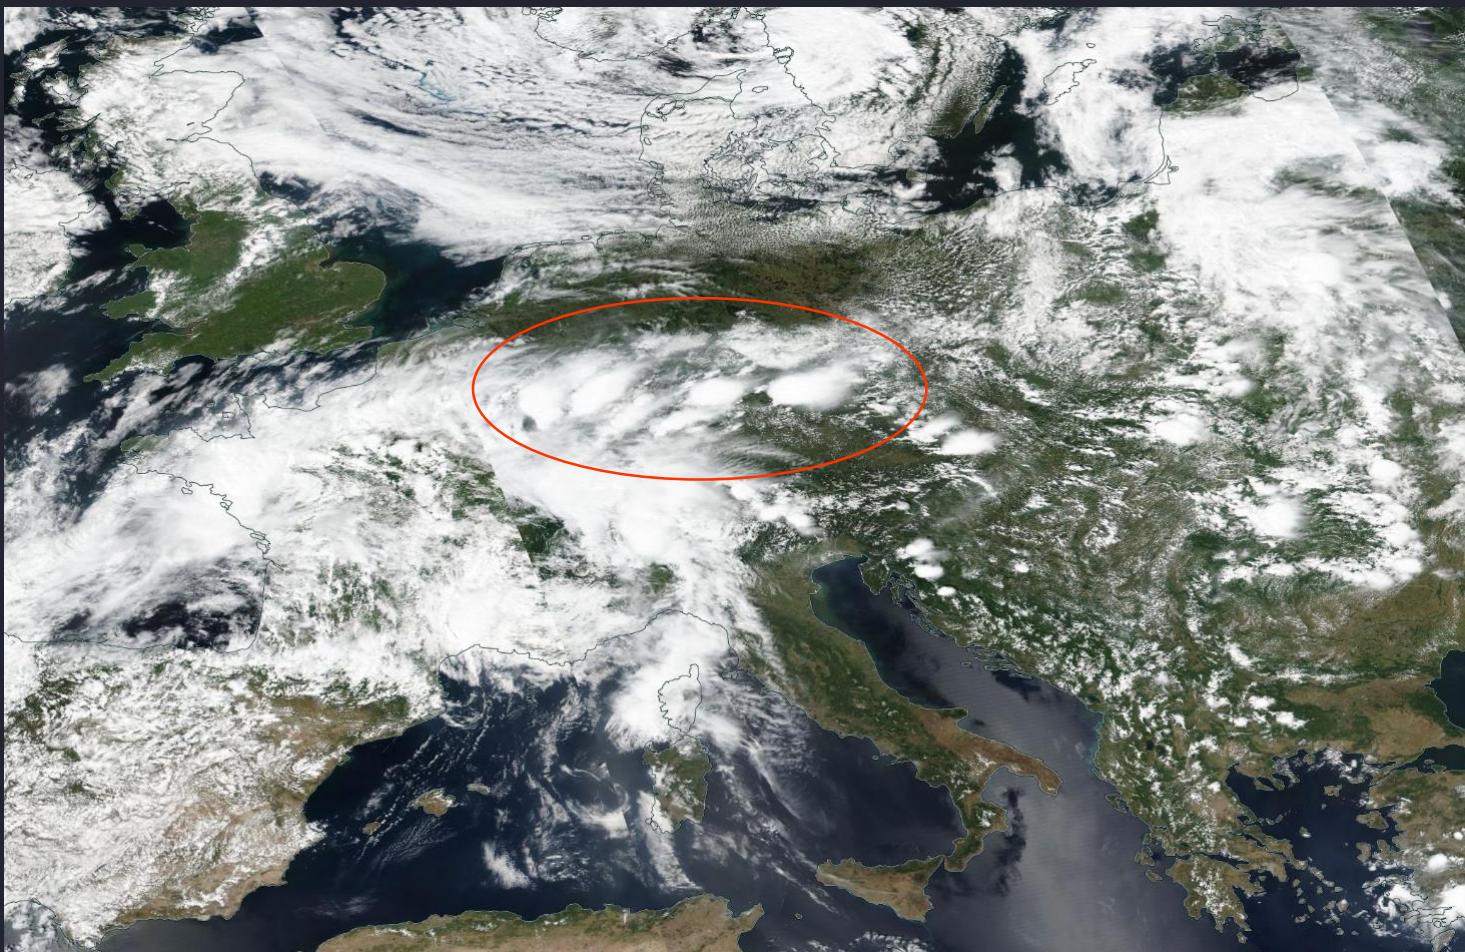

1.38 μm spectral band:

image source: [NASA EOSDIS Worldview](#)

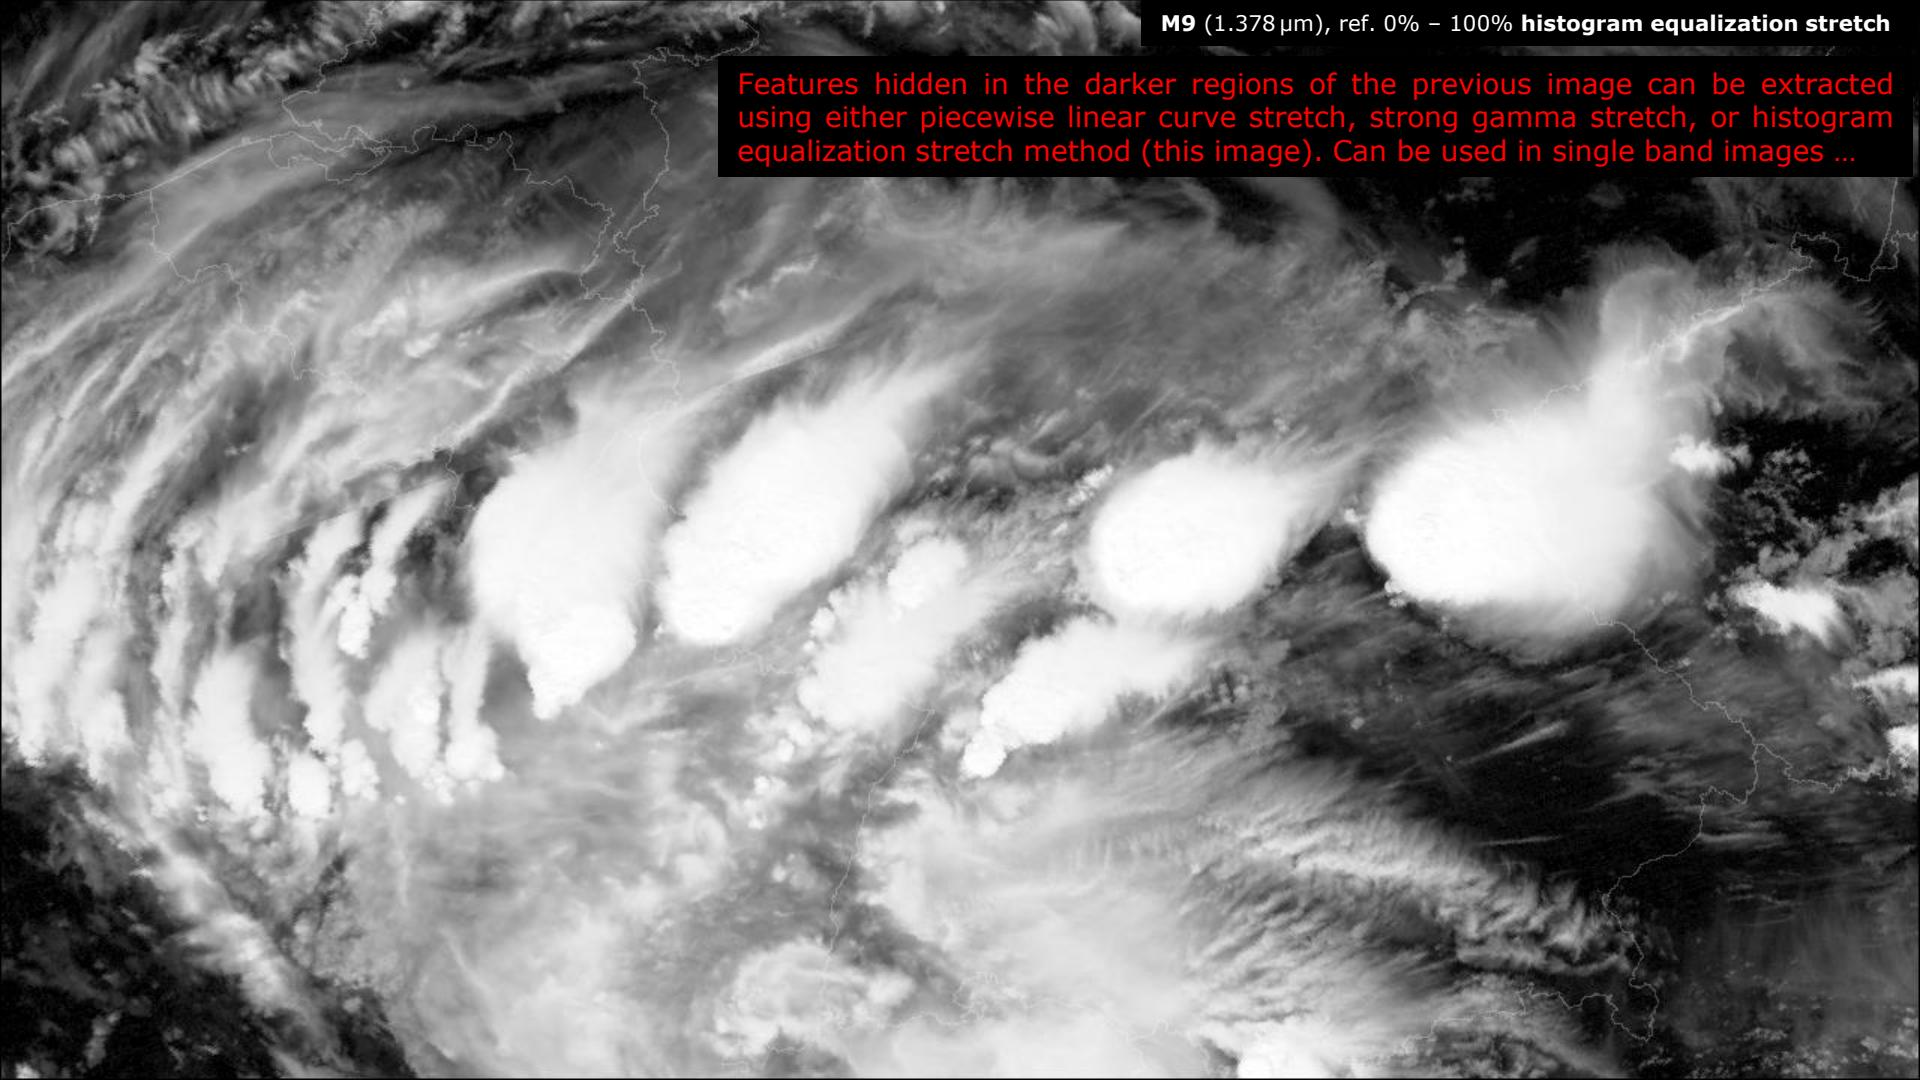

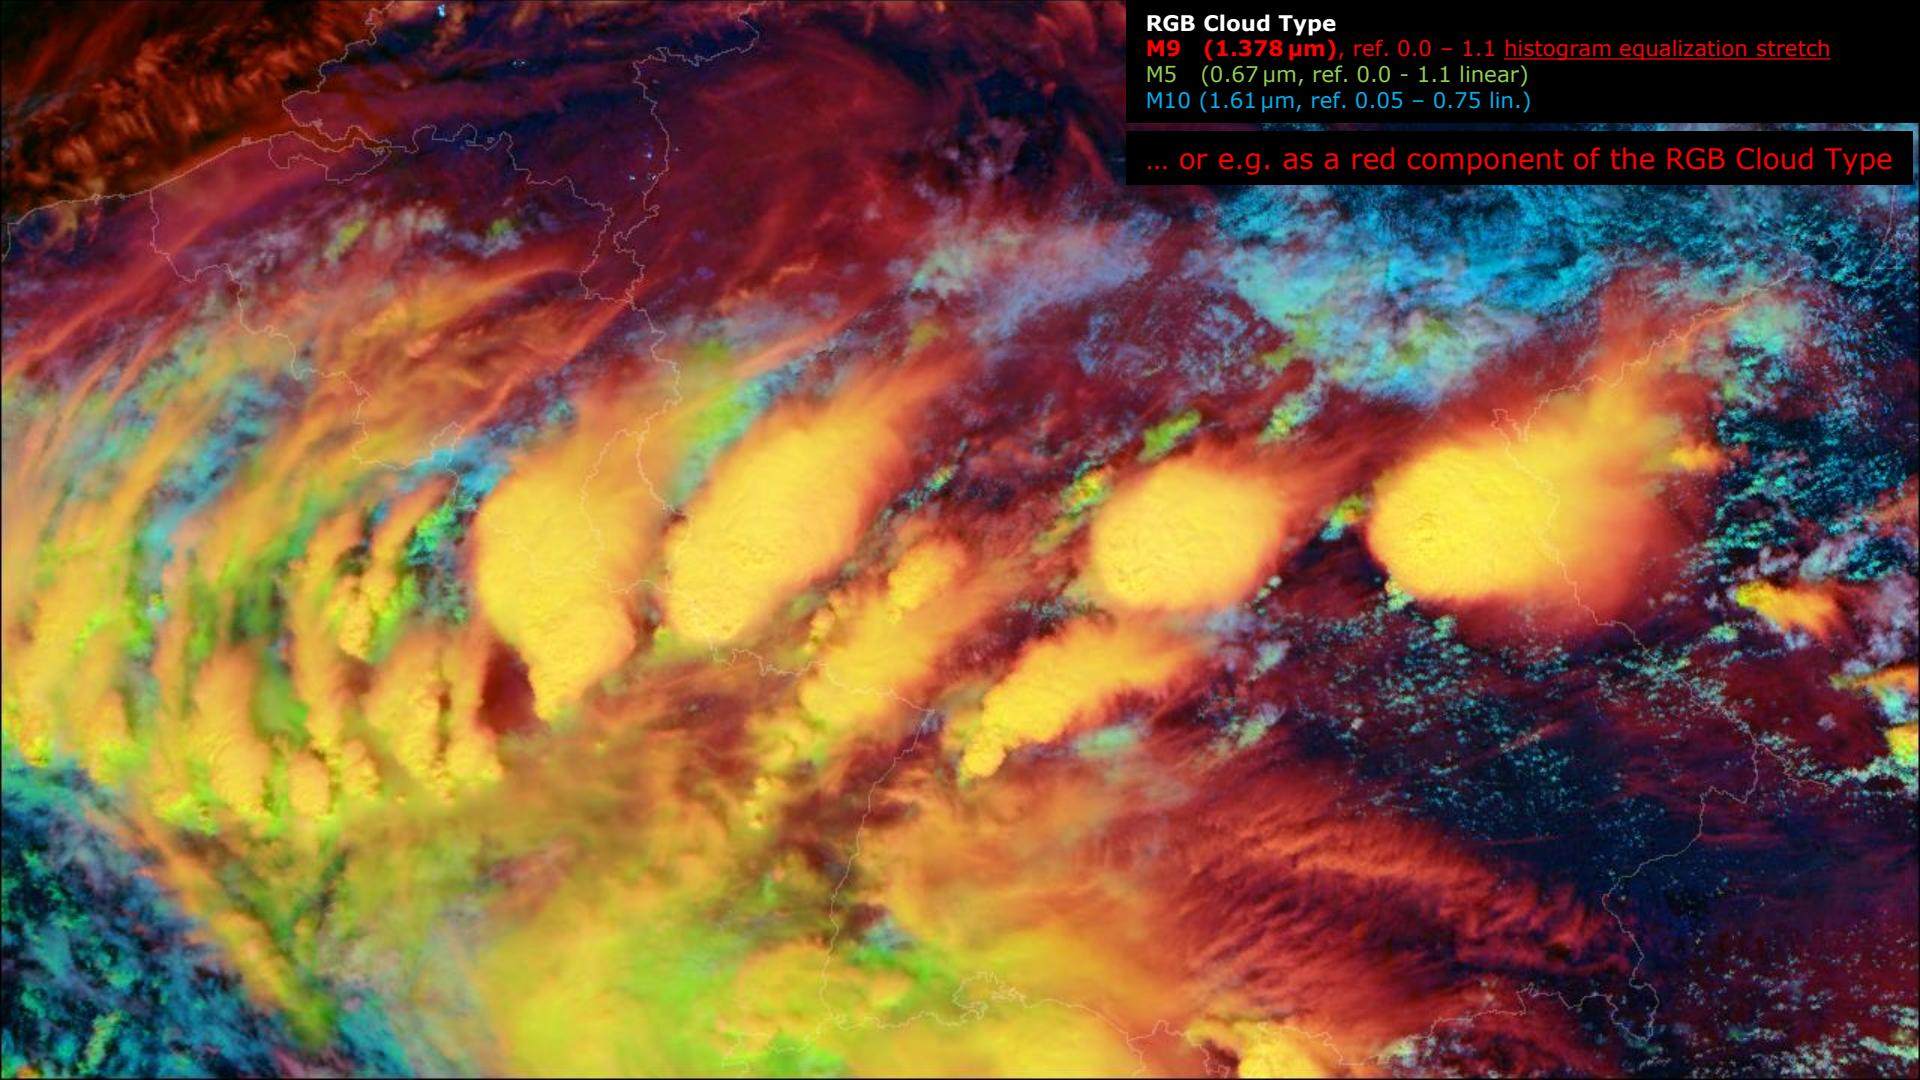

Dark parts of this image – strong absorption by tropospheric water vapor, masking everything at lower layers (lower clouds, aerosols, dust, ground). Only highest clouds (with higher opacity) can be seen here, using basic enhancement.

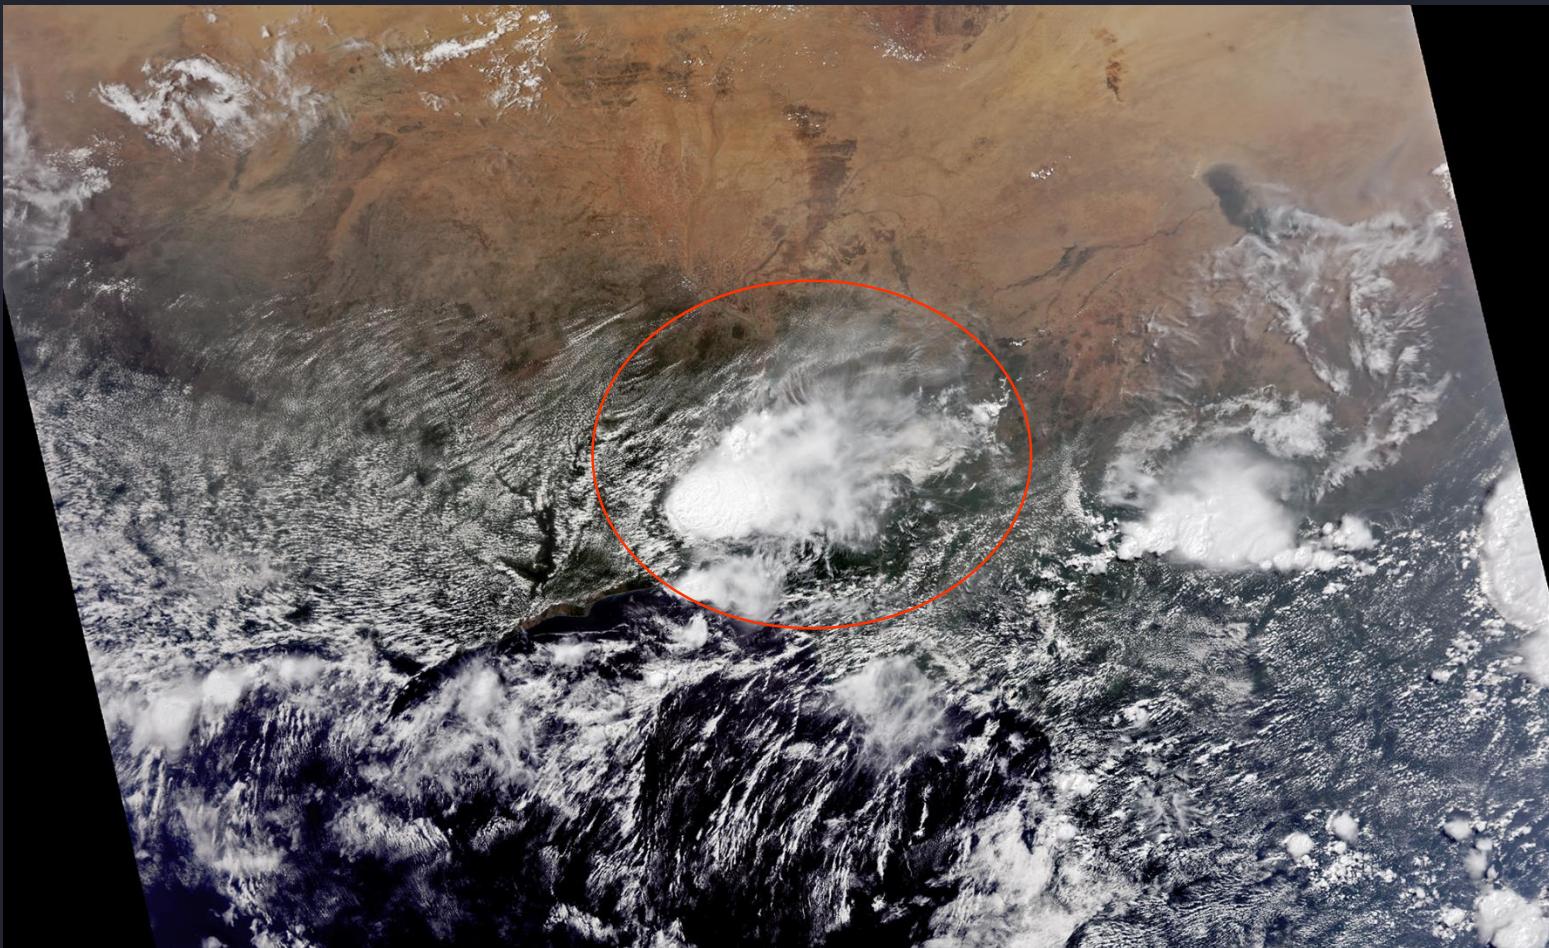

Features hidden in the darker regions of the previous image can be extracted using either piecewise linear curve stretch, strong gamma stretch, or histogram equalization stretch method (this image). Can be used in single band images ...

Brief summary:

- In most cases (including those not shown here), the 1.38 μm band and Cloud Type RGB provide about the same amount of information about thin cirrus as other bands and RGBs. However, to show the full extent of the thinnest cirrus, advanced enhancement methods need to be applied: piecewise linear stretch, histogram equalization stretch, or stronger gamma stretch (not tested yet).
- In some cases, the 1.38 μm band and Cloud Type RGB can show more of the thin cirrus, which escapes other methods (products) ... e.g. above desert areas (?).
- Up to now, no case with a plume extending beyond the regular anvil edge in the 1.38 μm band was found ... an impact of unfavorable timing of the NPP / NOAA-20 passes (shortly after local noon).
- The histogram equalization stretch and piecewise linear stretch can be useful for case studies, but (probably) not for operational use.
- Better option for similar studies – data from ABI, without the timing problem ...

Data:

- Suomi-NPP and NOAA-20 (JPSS-1) VIIRS M-bands, 750m pixel resolution
- cases selection: [NASA EOS Worldview](#)
link preconfigured for S-NPP (available since 24 Nov 2015) and NOAA-20 (since 25 Apr 2020)
- L1B data source: [NOAA CLASS archive](#)
- disadvantage: early afternoon orbit (ECT ~ 13:30 local time, asc.) » only very few mature storms at this time of the day, difficult to find good cases ...
- total of about 40 cases from 2012, 2013, and 2016 – 2021, from these ~ 30 cases processed tentatively, and from these ~ 20 cases processed in detail

Processing:

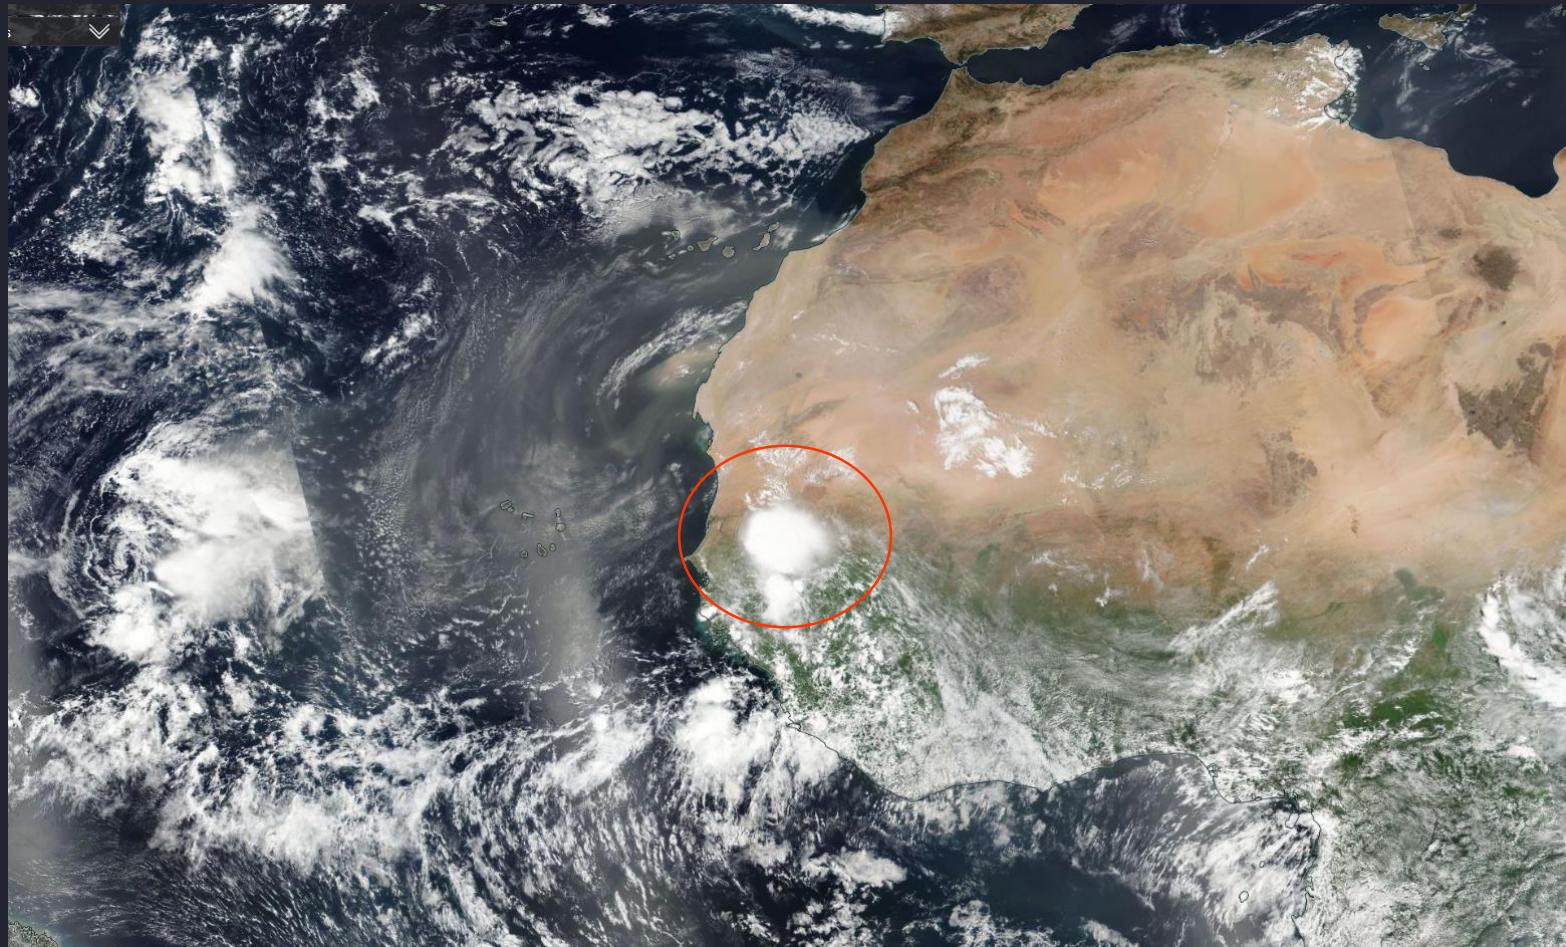

- [ENVI](#) and its [VCTK](#) plugin
- modest fine-tuning of some of the images in [Adobe Photoshop](#)
